HEAVY-DUTY ELECTRICAL SYSTEMS BASICS

Today's basic heavy-duty electrical system consists of batteries, a starting motor, an alternator, and the control circuit. The control circuit includes a magnetic switch, ignition switch, push button switch, and all the required wiring.

The batteries provide the high electrical current needed by the starting motor. The magnetic switch controls the battery current into the starter solenoid. The ignition and push button switch activate the magnetic switch, which in turn activates the starting motor. If all functions work properly, the engine should turn over. Mechanical energy from the running engine provides the power needed to operate the alternator. The alternator creates electrical energy that recharges the batteries and provides the current for the vehicle's electrical accessories and loads. The wiring should be of adequate size to carry the amount of current needed in each circuit.

When these components are properly matched, they provide a balanced electrical system that will perform well throughout its life expectancy.

SYSTEM COMPONENT FUNCTIONS

Battery

A battery is a storage unit that can store and produce electrical energy. With use, they gradually deteriorate and become less capable of performing their important task.

There are three basic types of batteries used in heavy duty electrical systems:

Filler Cap

These are lead- acid batteries with a high degree of a base element called antimony in the grid alloy. Because of this base element, they require frequent servicing, particularly the need for adding water.

Semi-Maintenance Free

These are conventional batteries with reduced amounts of antimony in the grid alloy. Consequently, servicing is reduced but water still must be added periodically.

Maintenance Free

These batteries use a lead- calcium grid alloy without antimony. They never need water, nor are provisions provided for adding water.

TECH TIPS

Starter

All starters, from the smallest to the largest are virtually the same. They are simply electrical motors that convert electrical energy into mechanical energy to crank the engine.

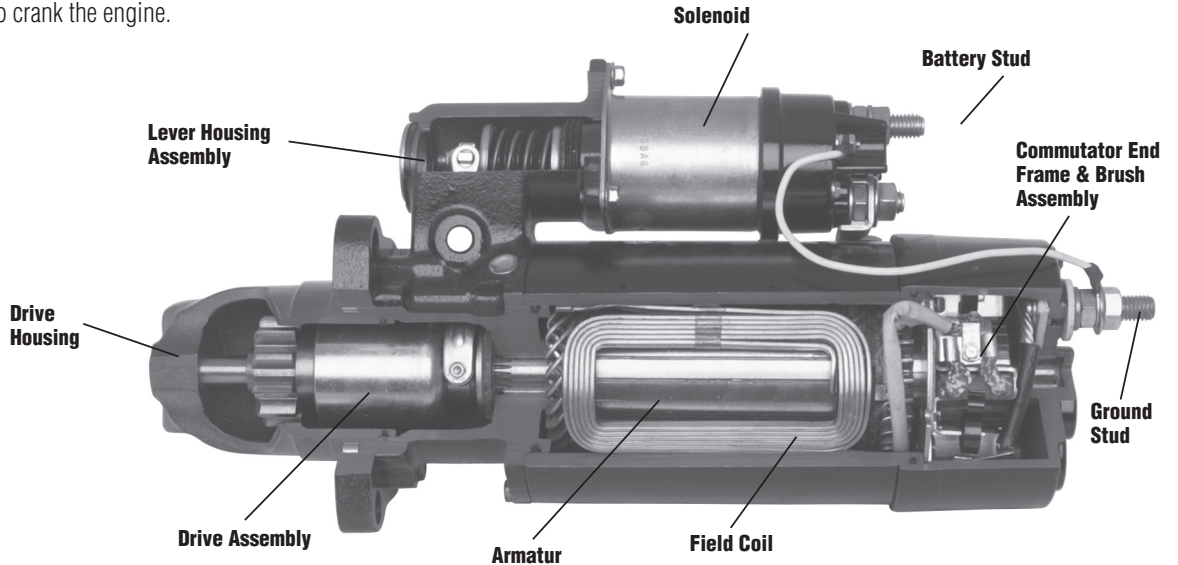

Figure 3

Alternator

An alternator is a generator that produces alternating current from mechanical energy. The use of rectifiers or diodes converts the alternating current to direct current. The direct current is used to maintain a charge in the battery and handle the electrical loads of the vehicle.

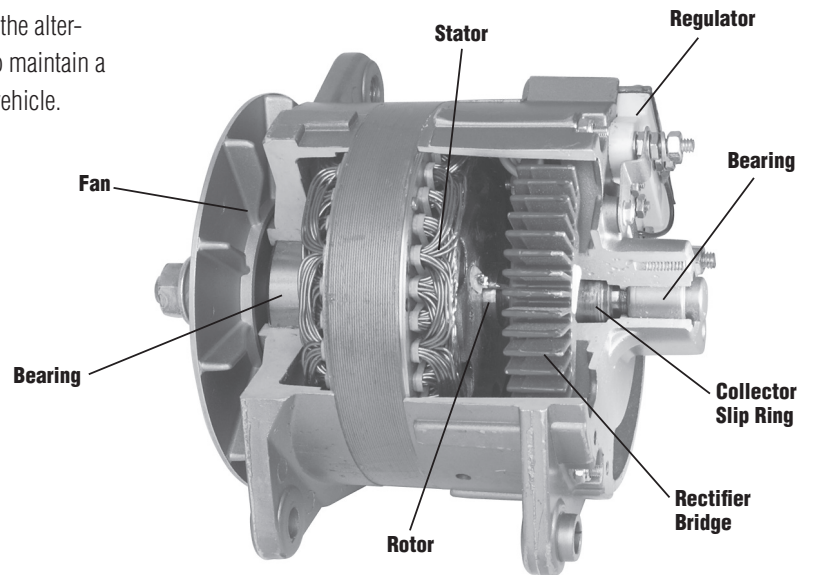

Figure 4

WIRING CIRCUITS

Cranking Circuit

The cranking circuit consists of large cables that carry the high starter current from the battery to the solenoid. Excessive voltage loss in the circuit causes slow cranking speeds, especially in cold weather. Slow cranking can lead to starter burn up if cranked over 30 seconds. Batteries that become deeply discharged can cause the same problem.

WIRING CIRCUITS (cont'd.)

Solenoid Control Circuit

The solenoid circuit consists of the wiring from the batteries through a push button or magnetic switch to the battery "SW" (switch) terminal of the starter solenoid and back to the battery. Excessive voltage loss in this current can cause the solenoid to shift in and out (chattering) which will result in the vehicle not starting. This condition can result in a burned contact disc or terminals of the starter solenoid. When a magnetic switch is used, excessive voltage loss will also cause this switch to open and close continuously. Batteries that become deeply discharged or worn out will cause the same condition.

Charging Circuit

The charging circuit consists of the wiring between the alternator and battery. Excessive voltage loss in the circuit will prevent the batteries from being properly charged. Complete failure of the charging circuit can cause alternator damage and/or failure.

Battery Cable Size and Connections

The connections and cable size have a significant effect on the electrical system. The jumper lines between batteries should be at least #00 gauge cable. The length of the circuit has a bearing on the amount of voltage loss which occurs in each cable. Be sure that all the circuits can handle the required load (**Refer to Table 1**). The total length of a circuit is the sum of both sides of the circuit.

Corrosion and loose connections, the two largest failure causes, can be minimized by taking precautions when installing cable ends. Many times these two go hand in hand. Corrosion will cause the connections to loosen. Corrosion travels through cables causing voltage losses. To prevent corrosion trouble, seal all exposed areas. When using crimp style ends that are open ended, seal by soldering them closed. Wire that is exposed to the elements should be sealed by using shrinkable tubing.

Figure 5

Energizing Alternators

Sometimes a new alternator will not charge because the magnetic field has been lost through long shelf life or jarring during shipping and handling. The magnetic field can be energized by momentarily connecting a jumper lead from the battery positive terminal (+) on the alternator to the relay (R) or indicator (I) terminal. This procedure will restore the normal residual magnetism.

TECH TIPS

BASIC ELECTRICITY

Current = Electron Flow

Current is the flow or movement of electrons. You can compare this to the flow of water. Without pressure (voltage), the current will not flow. Ampere (amps) is the unit of measure for electrical current.

Voltage = Electrical Pressure

Voltage provides the electrical pressure or force that causes current to flow. Voltage is the difference in electrical pressure between two points in a circuit.

Formulas and Definitions

All the electrical characteristics are interrelated. The basic formulas are:

$$I = E / R \quad \text{Amperes} = \text{Volts} / \text{Ohms}$$

$$E = R I \quad \text{Volts} = \text{Ohms} \times \text{Amperes}$$

$$R = E / I \quad \text{Ohms} = \text{Volts} / \text{Amperes}$$

Amps (Amperage) – measure of current flow in a circuit

Ohms (Resistance) – measure of resistance in a circuit

Volts (Electromotive force) – measure of the force that drives current flow in a circuit

Resistance

Resistance is a restriction of current flow. If resistance increases, current flow decreases. This can be detected by voltage loss in a circuit. Ohm is the unit of measure for resistance.

Magnetic Field

When forcing current through a conductor, a magnetic field is produced. Magnetic fields and direction of current flow are factors to consider when using ammeters, especially when using an induction pick up ammeter.

ELECTRICAL GLOSSARY

THE LANGUAGE OF CHARGING AND STARTING SYSTEMS

ALTERNATOR – A device which converts mechanical energy to electrical energy. It maintains the battery in a fully charged state.

AMPERE (AMP) – The unit measure of electrical current flow. This movement can be compared to the flow of water through a pipe.

ARMATURE – Any part moved by magnetic attraction or repulsion. An example is the armature in a starter.

BATTERY – A device for storing energy and converting chemical energy into electrical energy.

BRUSH – A block of conducting substance, usually made of carbon, which picks up or delivers electric current from, or to, the commutator or slipper ring.

BRUSH HOLDER – Holds the brushes on an alternator or starter in position on the commutator or slipper rings.

CHARGE RATE – The amperage flowing from the alternator to the battery.

CIRCUIT – The path over which a current of electricity flows.

COLD CRANKING AMPS – The number of amperes a battery at zero degrees Fahrenheit can deliver for 30 seconds and maintain a voltage of 1.2 volts per cell or higher.

COMMUTATOR – A cylindrical device mounted on one end of an armature shaft. It is composed of copper segments insulated from each other. The ends of the armature windings are soldered to pairs of segments.
